

OPUS.NET

Own the Infrastructure

**One Architecture. One Source Code License.
A Lifetime of Software Development.**

Life-Long Source Code License: NOK 7,000,000

Modern organizations repeatedly rebuild the same infrastructure.

Networking. Persistence. Serialization. Client/server communication. Concurrency.
Object distribution. Domain-model synchronization. Storage. Application infrastructure.

Then they rebuild it again for the next product.

OPUS.NET is designed to change that equation.

A Strategic Software Infrastructure Asset

At NOK 7 million, OPUS.NET is not positioned as a conventional developer framework. It is an enterprise software infrastructure asset for organizations that want long-term control over a foundational part of their software stack.

OPUS.NET is a general-purpose software infrastructure for building distributed .NET applications around a coherent object-oriented architecture. Instead of purchasing another black-box platform and becoming permanently dependent on somebody else's roadmap, the customer receives a life-long license to the OPUS.NET source code, subject to the license agreement.

The Commercial Proposition

The NOK 7,000,000 investment is not intended to be a monthly subscription, a per-developer charge, a per-server charge, or a per-application fee. The purpose of the model is to let a serious software organization make one strategic infrastructure decision and then exploit that foundation across a long-lived software portfolio.

**Give serious software organizations control of the
infrastructure beneath their applications.**

From Application to Infrastructure

A conventional development organization often thinks in terms of individual applications. OPUS.NET encourages a different perspective: build and understand the infrastructure once, then build products on top of it.

The architecture separates responsibilities across a multi-tier software chain, from the client-side domain model through binary communication, server processing, distributed middle-tier services, object-network processing, and physical persistence.

Applications can therefore concentrate increasingly on what makes them unique: their domain model, workflows, user experience, and business functionality. The infrastructure underneath becomes reusable intellectual capital.

Why Source Code Matters

Software dependencies create strategic dependencies. When an organization builds critical systems upon technology it cannot inspect or control, it also accepts the future decisions of the technology's owner. Products can be discontinued. Licensing can change. Prices can increase. Compatibility can disappear.

A source-code license changes that relationship. Within the rights granted by the license, the organization can inspect the implementation, understand it, modify it for internal requirements, maintain its own version, and integrate it into a long-term engineering strategy.

The customer is not merely acquiring functionality. It is acquiring technical sovereignty over a foundational part of its software stack.

The Economics of NOK 7 Million

Seven million Norwegian kroner is a substantial investment. The relevant comparison, however, is not the price of a small developer component. The strategic comparison is the total cost of designing, developing, debugging, documenting, integrating, securing, maintaining, and eventually replacing equivalent infrastructure over many years.

That calculation becomes especially important when an organization is developing not one application, but ten, twenty, or an entire generation of software products.

What would it cost to create, validate, maintain, and evolve equivalent infrastructure over its entire useful life?

Built for Organizations That Build

OPUS.NET is intended for organizations for which software is strategically important: software companies, technology companies, industrial enterprises, financial organizations, research institutions, government technology programs, and other organizations maintaining substantial proprietary software portfolios.

It is particularly relevant where long-term architectural control is more important than permanent dependence upon a hosted platform or opaque third-party framework.

Not SaaS

The software industry increasingly asks customers to rent infrastructure indefinitely. OPUS.NET takes a different position.

Own your application strategy.

Control your infrastructure.

Keep access to the source.

Build for the long term.

A life-long source-code license allows OPUS.NET to be evaluated as an investment in software capability rather than simply another recurring software expense.

One Foundation, Many Products

The real potential of OPUS.NET appears when the same infrastructure supports multiple applications. A company can build its first product on the architecture, then its second, then its fifth. The domain models, interfaces, and markets may change while substantial parts of the underlying infrastructure remain conceptually consistent.

The organization begins accumulating architectural knowledge instead of repeatedly discarding it. Over a long enough horizon, that accumulated knowledge can become one of the most valuable outcomes of the original investment.

The Product Is Control

OPUS.NET can be described in terms of networking, serialization, domain objects, persistence, distribution, concurrency, and storage. But those are implementation concepts. The strategic product is simpler: control.

Control over the source code. Control over modification. Control over deployment architecture. Control over technical direction. Control over how long the infrastructure remains useful.

OPUS.NET

**Enterprise software infrastructure for organizations that
intend to keep building.**

**Life-Long Source Code License
NOK 7,000,000**

**Don't rent the foundation of your software future.
Build on infrastructure you can control.**

Commercial note

A final license agreement should precisely define source-code rights, internal modification rights, the legal entities covered, redistribution restrictions, support and maintenance, upgrades, intellectual-property ownership, escrow where applicable, and the rights to sell applications created using OPUS.NET. These terms are essential to the value proposition of an enterprise source-code license.
